TRANSPORT Simulation Environment

Introduction

Thomas Kempka
GFZ German Research Centre for Geosciences
University of Potsdam

Why Yet Another Numerical Simulator (YANS), not even providing the features of existing ones?

- We have extensively tested {put any transport simulator here} and are not satisfied with the capabilities of any of these
- We do not want to spend multiple months to understand simulators other people have developed (we have been doing this over the past 14 years :-/)
- We want to be flexible and couple/integrate processes as required (T, H, C, M?!, R, B, E)
- We want to understand what we are doing and especially any potential limitations, so that we do NOT leave our scientific work to black boxes
- We have decided that we would like to abandon complex grids, but rather focus on processes and their coupling (→ FDM suffices)
- Most of us are really tired of developing workarounds to get coupled process simulations working, producing questionable results
- We need a simple tool that WE are able to understand, use and adapt

TRANSPORTSE (YANS) benefits in a nutshell...

- FDM implementation of coupled density-driven Darcy flow, heat and species transport < 1500 lines(!) of Python code
- Explicit, semi-implicit and fully implicit solution of coupled equations (simple iterative SOR Gauss-Seidel solver)
- Just-in-time (JIT) compilation (numba) provides execution times in the same order of C/C++/FORTRAN codes
- EOS implementation is straight forward (parallelisation feasible)
- Chemical module coupling straight forward (parallelisation feasible)
- Runs in parallel on multiple CPU cores already scales with 2 cores on your lousy ;-) laptop (tested with 80 cores on GFZ cluster)
- Very efficient and simple model parametrisation thanks to numpy
- Generally very good Python code readability supports understanding of TRANSPORTSE implementation and eases modifications
- HOWEVER, crap in → crap out: you are the modeller and responsible for your work

TRANSPORTSE solves coupled systems of equations for density-driven Darcy flow, species and heat transport

Density-driven Darcy flow (Pressure formulation)

$$\rho_f\left((1-\phi)\alpha+\phi\beta\right)\frac{\partial P}{\partial t}=\nabla\left[\frac{k\rho_f}{\mu_f}\left(\nabla P-\rho_f g\nabla z\right)\right]+W$$

Diffusive and advective species transport (one PDE system for each species)

$$\phi\frac{\partial C}{\partial t}=\nabla(\phi D\nabla C-qC)+Q$$

Conductive and convective heat transfer

$$\left((1-\phi)c_r\rho_r+\phi c_f\rho_f\right)\frac{\partial T}{\partial t}=\nabla\left[\left((1-\phi)\lambda_r+\phi\lambda_f\right)\nabla T-qc_f\rho_f T\right]+H$$

Non-linearity due to parameter dependency on pressure, temperature and dissolved species/single-phase fluid composition and chemical reactions (R)

$$\rho_f(P,T,C),\beta(P,T,C),\mu_f(P,T,C),\phi(R),k(\phi),c_r(T),c_f(P,T,C),\lambda_r(T),\lambda_f(P,T,C)$$
